BIAP Global — Investor Proposal

Oct 12, 2026 · @Khabat Setaei

1. Executive summary

BIAP Global is a pre-revenue, working research prototype that analyses listed companies in six markets (US, UK, France, Italy, Sweden, Norway) and tells the investor how much to trust each result, not only what the result is. We are seeking seed funding to turn a technically deep prototype into a validated, licensed, commercially ready product within 24 months.

The problem. Investors face fragmented filings, expensive professional tools, and AI tools that sound confident on thin evidence. Distress, credit and portfolio fit are analysed in separate products.

The product. A pipeline from official filings and market data to normalised company records, evidence verification, multi-agent analysis, distress and credit-risk indicators, decision governance and portfolio suitability. Its distinguishing rule: the system can answer **NO_RECOMMENDATION** when evidence or calibrated confidence is too weak.

What exists today (verified in the repository, 12 Oct 2026).

- A Python analysis service (about 35,000 lines outside tests) with a country-pack architecture and dozens of source adapters, including SEC EDGAR/XBRL, ESEF filings and Nasdaq Nordic.
- Core analysis agents, an evidence agent, a portfolio agent, and Altman/Zmijewski-style distress logic.
- A deployed production service at biap.dadashi.no/global and an Android app (version 0.3.21) built by CI.
- A production evidence audit against live data, with per-market results published in the repository.
- Roughly 2,000 commits since June 2026 and 900+ automated tests reported in the project's own status notes.

What does not exist yet. Revenue, paying users, customers, a validated track record, backtests, market-data redistribution licences, a device-tested app release, patents, or regulatory authorisation. Nothing in this document claims otherwise.

The ask. A milestone-tranched seed round (framework in section 10), released against evidence gates: reconciliation and device QA, then scientific validation, then a private beta with measured demand, then licensing and compliance. Amount and valuation are deliberately left open until the missing evidence in section 12 is gathered.

2. Business proposal

BIAP Global sells **evidence-aware investment research**: every output carries its sources, freshness, gaps and a confidence state, and weak evidence produces an abstention instead of a guess.

Problem. Public-company data is split across exchanges, regulators and vendors. Comparing issuers across currencies, accounting regimes and share classes is hard. Retail and small-professional users either pay institutional prices or use screeners that hide data quality.

Solution. One normalised company record per issuer, fed by official filings where available, passed through verification and analysis agents, and presented with separate answers to four questions: how good is the evidence, how attractive is the company, how confident is the assessment, and does it suit this investor's portfolio.

Status legend used throughout this document. *Existing* = found in the repository or production audit. *Partial* = built but incomplete or unvalidated. *Planned* = not built. *Unverified* = claimed in the brief, not confirmed.

Capability	Status	Basis
Country-pack architecture and normalised company schema	Existing	`GLOBAL_ARCHITECTURE.md`, `country_packs.py`, `models.py`
Filing and market-data adapters (SEC EDGAR, ESEF, Nasdaq Nordic, Companies House, many others)	Existing, uneven coverage	`analysis/global_markets/` (100+ modules)
Fundamental, risk, forecast and comparison agents	Existing	`core_agents.py`
Evidence/verification agent with PASS / WARN / BLOCK states	Existing	`agents.py`, `evidence_contract.py`; audit files in `docs/audits/`
Governance and `NO_RECOMMENDATION` abstention	Existing; thresholds not independently calibrated	`governance.py`, `decision_support.py`
Distress models (Altman variants, Zmijewski)	Existing; not validated against defaults	`distress.py`

Capability	Status	Basis
Corporate credit scoring	Partial: report-only adapter, not part of the investment score; source design is a draft awaiting founder acceptance	`credit_scoring.py`
Portfolio agent with investor profile and duplicate-issuer guard	Existing; not backtested	`portfolio_agent` in `agents.py`
Android app 0.3.21, CI-built and published	Existing; physical-device regression testing still pending	`mobile-global/`, CI workflows
Six-market scope (US, GB, FR, IT, SE, NO)	Existing as a scoped v1; Germany excluded pending data	v1 release audit, 11 Oct 2026
Brief's six scoring dimensions (adds Valuation, Quality, Liquidity)	Unverified: code shows four core agents plus evidence, distress and portfolio	verify against source before publishing
Backtests, calibration, accuracy, returns	Planned: none exist	section 8
Paying users, revenue, customers	None	section 12
Live brokerage execution	Out of scope; research and paper only	architecture principle 5

3. Competitive landscape

BIAP Global does not out-data the incumbents; its opening is a narrow one: auditable, abstention-capable analysis for users priced out of institutional tools. Competitor names below come from general market knowledge, not a fresh survey, and must be re-checked (features, pricing, coverage) before external use.

Segment	Examples	Their strength	Gap BIAP targets	Honest risk to BIAP
Institutional terminals and data	Bloomberg, FactSet, S&P Capital IQ, LSEG Workspace	Depth, breadth, licensed data, trust	Price and complexity for individuals and small firms	Unmatched data quality and distribution; BIAP cannot compete on coverage
Retail research and screeners	Morningstar, Simply Wall St, Koyfin, Stockopedia, TIKR	Polished UX, brand, large user bases	Per-metric provenance, freshness and explicit abstention are rarely shown	Fast followers; users may not pay for transparency
AI research assistants	AlphaSense, Perplexity-style finance tools, broker chatbots	Natural-language search over filings and news	Structured, rule-governed scoring with reproducible inputs	Large-model vendors can add provenance features quickly
Credit and distress analytics	Rating agencies, Moody's and S&P analytics, Altman-style vendor scores	Authority and regulatory standing	Cheap, transparent, equity-linked indicators	BIAP scores are analytical estimates, never ratings
Robo-advisers and portfolio tools	Wealthfront-, Nutmeg-style services	Execution, regulation, simplicity	Research-grade explainability	They are regulated advisers; BIAP is not

Positioning. BIAP is a *research and decision-support layer*, not a broker, rating agency or adviser. The defensible claim is the combination: six-market normalisation, evidence states, abstention governance, distress/credit context and portfolio suitability in one auditable pipeline. Superiority over any named competitor is **not demonstrated** and must be tested in the private beta and the validation programme.

Likely moat, ranked by durability. (1) Accumulated adapter knowledge and edge-case handling across jurisdictions; (2) a growing audited evidence history; (3) calibrated confidence once validated; (4) user trust from a visible abstention record. Code alone is a weak moat, which is why validation and data relationships matter.

4. Target market and customer segmentation

The beachhead is the self-directed European investor and the small professional who needs more rigour than a screener but cannot afford an institutional terminal. No market-size figure is given here: a defensible TAM/SAM/SOM must be built bottom-up from sourced user counts and price points, and none has been compiled yet.

Segment	Need	Buyer	Fit today	Priority
Self-directed individual investors (Nordics, UK, FR, IT, US)	Explainable research, risk and data-quality context	Self	Good: mobile app and scan exist	1: beachhead
Independent analysts, newsletter writers, small advisers	Auditable comparisons, exportable evidence	Self or small firm	Partial: needs export, API, reliability SLAs	2
Small investment firms and fintechs	Embedded research or scoring via API	Firm	Partial: no API contract, licensing or SLA	3: after licensing
Universities and research groups	Reproducible distress, credit and abstention research	Department or grant	Good: evidence ledger suits research	2: low revenue, high credibility
Iran pilot	Distinct data and operational stack	Local partner	Separate codebase path on `main`	Deferred: see risks

Why start with individuals and researchers. Both can be reached without data-redistribution contracts that a B2B offer would trigger, and both give the structured feedback needed for calibration. B2B follows once licences are secured.

Customer discovery plan (not yet done). 30 to 50 structured interviews across segments 1 to 3, a landing-page waitlist with a stated price test, and a 50 to 100 user private beta with usage and willingness-to-pay measured.

5. Revenue model (hypotheses to validate)

Current revenue is zero. The model below is a testing plan: price points are illustrative starting hypotheses for the private beta, not forecasts, and every one needs data-licence cost analysis first.

Tier	Audience	Contents	Illustrative test price	Gate to launch
Free	Individuals	Delayed scan, evidence state, limited agent detail, daily analysis cap	0	Beta
Pro	Individuals, analysts	Full agent breakdown, distress and credit context, portfolio module, watchlists, exports	EUR 10 to 25 per month	Calibration published; device QA done
Professional	Analysts, advisers, small teams	Seats, evidence export, comparison tools, audit trail	EUR 50 to 150 per seat per month	Licensing and terms cleared
API / B2B licence	Fintechs, small firms	Scoring and evidence endpoints, SLA	Custom, annual	Redistribution licences in place
Academic	Universities	Reproducible datasets and ledger access	Grant-funded or discounted	Data terms permit research use

Economic constraint to resolve first. Gross margin depends on the cost of licensed market and fundamentals data, which has not been priced. If redistribution licences cost more than early revenue, the plan shifts to official-filings-first data with delayed prices.

Metrics to track from beta. Activation, weekly retention, free-to-paid conversion, willingness to pay, cost per active user (data plus compute plus LLM calls), and support load. No target is asserted until baselines exist.

Regulatory framing. Pricing and marketing must keep BIAP outside personalised investment advice or rating-agency activity; this needs a legal opinion in each launch jurisdiction.

6. Technology and intellectual property

Architecture (existing). Provider adapters normalise each market into one schema, so analysis agents contain no exchange-specific logic. Data flows from instrument universe and official filings into a normalised company record, then into core agents, the evidence agent and the portfolio agent, and finally to the API and Android app. Execution is paper or human-approval only.

Layer	Implementation found in repository
Analysis service	Python, about 35,000 lines outside tests, with 200+ test files
Data adapters	SEC EDGAR/XBRL, ESEF/OAM filings, Nasdaq Nordic, Companies House, GLEIF and ESMA FIRDS identity, plus many exchange-specific modules
Agents	Fundamental, risk, forecast, comparison, evidence, portfolio, distress; report-only credit adapter
Governance	Evidence states (PASS / WARN / BLOCK), abstention, duplicate-issuer guard, stale-share-count guard
Delivery	Backend on a VPS, Expo/React Native Android app, GitHub Actions for build, deploy and audit
Provenance	Field-level "not tagged" versus "withheld" distinction, analysis ledger, audit reports in `docs/audits/`

Technical credibility signals. Production audits that name and root-cause individual issuer failures instead of hiding them; explicit rules that missing data lowers confidence rather than being fabricated; and a test suite the project reports at 900+ passing tests (a figure from its own status notes, not independently run for this document).

Technical debt to disclose. The Python service carries Iran-era modules alongside Global code; there are 173 CI workflows, about 77 of them one-off probes; operations run on a single VPS; some data files and SQLite stores sit near the code. A cleanup and hardening pass is part of the roadmap.

Intellectual property: honest position.

- **Owned today:** the source code, architecture, adapters, evidence contract and audit corpus, assuming sole authorship by the founder. Contributor and contractor assignment must be confirmed.

- **Not owned:** market data, filings content and exchange data, which are licensed or public and carry usage terms. Third-party code, including Expo (MIT), keeps its own licence.
- **Gaps:** the repository has no top-level licence file; no patents are filed or claimed; no trademark search or registration for "BIAP" or "Kiasha" has been done; the credit-scoring adapter derives from a separate repository (`dma-agent`) whose ownership and acceptance status must be settled.
- **Strategy:** protect through trade secrets, copyright and data-relationship moats, not patents. Seek legal advice on whether the evidence-governance method is patentable in the EU, and on trademark clearance before any launch.

7. Founder's technical vision and competitive potential

The founder's thesis: the next useful layer in investment research is not a better prediction but a better statement of **what is known, how well, and what is not**. Most tools rank first and caveat later; BIAP is built to verify first, and to decline when it cannot.

Vision in four commitments, each visible in the code.

1. **Evidence before opinion.** An instrument without verified identity, fresh price and official filing evidence cannot become a BUY candidate; it still gets labelled, non-official metrics.
2. **Abstention is a feature.** `NO_RECOMMENDATION` is a first-class output when confidence or agent agreement is weak.
3. **Adapters, not hard-coding.** Each country is a pack of providers; the analytical core is shared, so a new market is an integration task, not a rewrite.
4. **Measured error.** No live use until each market has backtests, walk-forward validation and paper portfolios.

Evidence of execution capability. About 2,000 commits from June to October 2026; a six-market release scoped and audited on live data; named root-cause fixes for individual issuers (for example gross finance-cost handling, share-count staleness, bank distress treated as not applicable); and an honest status trail that records "release-ready: NO" when it was not. That candour is itself a credibility asset for investors.

Competitive potential, stated carefully. If validation shows that abstention improves the reliability of the remaining recommendations, BIAP has a differentiated, testable claim that incumbents do not currently foreground. If it does not, the product is still a low-cost, multi-market research tool with strong provenance. The upside is unproven; the downside is bounded by tranche-based funding.

What the founder still needs. A quantitative-finance partner to own validation, a commercial lead for licensing and go-to-market, and a security and compliance adviser. The team section of any pitch must show these as hires or advisers, not as existing capacity.

8. Scientific validation and risk management

No accuracy, return or calibration result exists today. The validation programme below is the central deliverable of the first 12 months, and its results will be published whether favourable or not.

Validation programme

1. **Point-in-time dataset.** Reconstruct what was knowable at each date from filing timestamps; no look-ahead from restated numbers.
2. **Backtest, 3 to 5 years.** Per market, with survivorship-bias controls, transaction costs, currency effects and risk-adjusted benchmarks.
3. **Out-of-sample and walk-forward.** Thresholds fixed before testing; a held-out final period touched once.
4. **Calibration.** Reliability curves for confidence scores; test whether abstention raises the hit rate of remaining calls.
5. **Ablation.** Remove each agent in turn and measure the change, to show which components earn their place.
6. **Distress validation.** Compare distress flags with later defaults, delistings or restructurings; report AUC and false-alarm rates.
7. **Reproducibility audit.** An independent reviewer reruns a sample from raw sources.

A university or independent quant partner should co-own steps 2 to 6 so the results are credible.

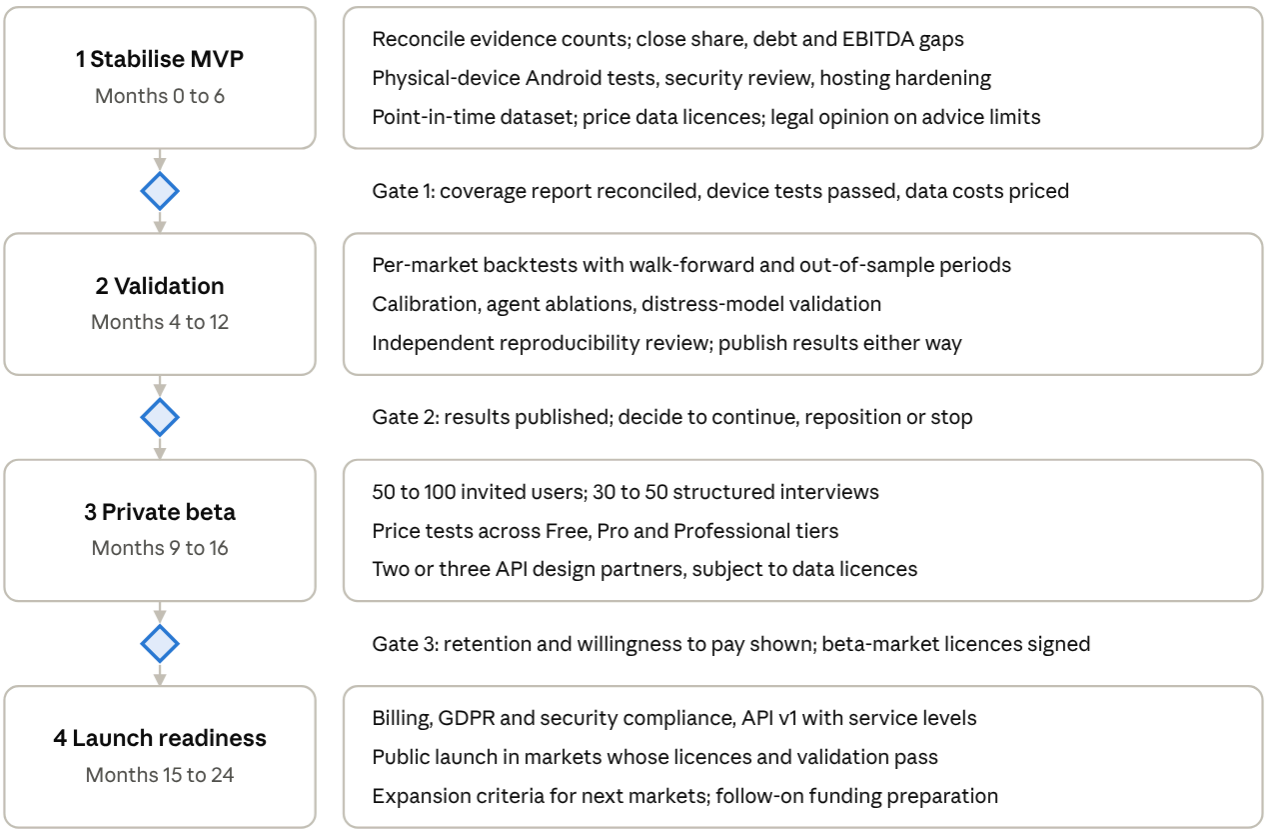

Risk register

Risk	Likelihood	Impact	Mitigation
Validation shows no predictive edge	Medium	High	Reposition as provenance and research tool; stage-gated funding limits exposure
Data licensing costs exceed revenue or block redistribution	High	High	Official-filings-first design; negotiate licences before B2B; delayed prices

Risk	Likelihood	Impact	Mitigation
Regulatory classification as investment advice or rating	Medium	High	Research-only framing, disclaimers, legal opinion per country, no personalised orders
Sanctions and compliance exposure from Iran-related work	Medium	High	Keep Iran pilot legally and technically separate; seek sanctions counsel before any pilot; investors should see this disclosed
Source fragility (site changes, rate limits, blocked scraping)	High	Medium	Prefer official APIs and bulk files; monitoring; freshness states
Single-founder and single-server dependency	High	High	Hire second engineer; backups, infrastructure as code, documented runbooks
LLM cost, availability or provider billing failure	Medium	Medium	Deterministic core; LLM only for explanation; budget caps
Security and privacy (accounts, API keys)	Medium	High	External security review, secrets management, GDPR assessment
Android quality	Medium	Medium	Physical-device regression suite before beta
Over-claiming	Medium	High	Claims register; every public statement mapped to evidence

9. 24-month development and commercialisation roadmap

Funding is released against three evidence gates over 24 months

Phases overlap in time and are not drawn to scale. Month 0 = first tranche received.

24-month roadmap · 4 phases, 3 gates

Each gate is a decision point: if its evidence is missing, the next tranche is not released and the plan is revised. Month 0 is the first tranche; all durations are planning assumptions, not commitments.

10. Milestone-based funding and use of funds

The round size is **not set**: it must come from a bottom-up budget (salaries, data licences, cloud, legal) that does not yet exist. This framework fixes the structure so that each tranche buys down a specific risk and nothing is released on narrative alone. Shares are indicative planning weights to be replaced by a real budget.

Tranche	Funds the phase	Risk it retires	Release condition	Indicative share of round
T1	Stabilise MVP (months 0 to 6)	Data completeness, device quality, licence costs unknown	Signed budget, founder and adviser agreements, IP assignment confirmed	25%
T2	Validation (months 4 to 12)	No evidence the method works	Gate 1 met	30%
T3	Private beta (months 9 to 16)	No evidence anyone will pay	Gate 2 met and results published	25%
T4	Launch readiness (months 15 to 24)	Compliance, licensing, scalability	Gate 3 met	20%

Use of funds by category (shares to be budgeted).

Category	What it covers	Guidance
Engineering and operations	Second engineer, infrastructure hardening, mobile QA, security review	Largest share, front-loaded
Quantitative validation	Quant researcher or university partnership, compute, independent reproducibility review	Second share; protected from cuts
Data licensing	Market-data and fundamentals licences for beta and launch markets	Quote-driven; may reshape scope
Legal and compliance	Advice and rating-line opinions, GDPR, sanctions advice, trademarks, terms	Front-loaded
Go-to-market	Customer discovery, beta operations, content, light marketing	Mostly from T3
Founder and general	Salary, accounting, insurance	Set to local norms

Non-dilutive and partner routes worth pursuing in parallel. European innovation and AI-for-finance grants, national innovation agencies (the Nordic ones are natural fits), university research partnerships, and accelerator programmes. Eligibility, amounts and deadlines must be checked against current calls; none are assumed here.

What the investor receives at each gate. A short evidence pack: coverage report, validation results, beta metrics, licence status, and an updated risk register.

11. Investor pitch deck outline

Twelve slides, each with one claim and its proof status. A slide that cannot show proof says so openly.

1. **Title.** BIAP Global: financial research that shows its evidence. One-line description; stage stated as pre-revenue prototype.
2. **Problem.** Fragmented data, expensive tools, confident AI on thin evidence.
3. **Solution.** Evidence, then analysis, then governed decision, then portfolio fit. Show the abstention rule.
4. **Product demo.** Three screens: a PASS company, a BLOCK company with the reason, and a portfolio suitability result. Use real production output.
5. **How it works.** Architecture diagram: adapters, normalised record, agents, governance.
6. **Traction, honestly.** Six markets covered, production audit results, build velocity, app 0.3.21. Revenue and users shown as zero, with the beta plan.
7. **Market and customers.** Beachhead segments and the bottom-up sizing once built.
8. **Competition.** The landscape table and the defensible gap. No superiority claim.
9. **Business model.** Tiers as hypotheses with the test plan and data-cost economics.
10. **Validation and risk.** Backtest and calibration programme; top five risks with mitigations.
11. **Roadmap and gates.** The 24-month diagram with tranche releases.
12. **Team and the ask.** Founder, advisers to be added, round structure, use of funds.

12. Missing evidence before fundraising

These items separate a credible pitch from a promising prototype. Tick them off as they are produced.

Product and data

- [ ] Reconciliation of analysis counts (for example Stockholm: 402 deep analyses versus 150 Evidence PASS) with defined populations and statuses

- [ ] Per-market coverage table: instruments in the universe, analysed, PASS, WARN, BLOCK, with dates
- [ ] Confirmed agent inventory and scoring dimensions against current source (the brief lists six; the code shows four core agents plus evidence, distress and portfolio)
- [ ] Physical-device Android regression results; the 0.3.21 device test is still pending
- [ ] Independently rerun test suite and a recorded demo on production

Scientific

- [ ] Point-in-time backtest, calibration curves and ablations (none exist)
- [ ] Evidence that abstention improves the quality of remaining recommendations
- [ ] Distress-model validation against real defaults

Commercial

- [ ] Customer interviews, waitlist and willingness-to-pay data
- [ ] Bottom-up market sizing with sources
- [ ] Data-licence quotes and the resulting gross margin per user
- [ ] Verified competitor feature and price comparison

Legal, IP and team

- [ ] Company registration, cap table and founder IP assignment; contributor agreements
- [ ] Open-source licence decision for the repository; trademark search for BIAP and Kiasha
- [ ] Legal opinion on the advice and credit-rating boundaries in each launch country
- [ ] Sanctions and compliance review of any Iran-related activity, with disclosure to investors
- [ ] Clarified ownership and acceptance status of the credit-scoring source (`dma-agent`)
- [ ] Security and GDPR review; named advisers or hires for quant, commercial and compliance

Financial

- [ ] 24-month budget by category, current burn and runway, and the round size derived from them

Verification note. This proposal was prepared from the supplied brief plus a read of the repository on 12 Oct 2026 (local clone, branch `feat/se-per-class-market-cap` , with status notes from `feat/biap-global`). Competitor information, grant availability and legal points were not independently researched and are labelled accordingly. Test counts, audit figures and commit counts come from the project's own files and were not re-run.
